Estimating Join Selectivities using Bandwidth-Optimized Kernel Density Model

M. Kiefer, M. Heimel, S. Breß, V. Markl

Problem & Motivation

• Task: Estimating selectivities for queries of queries of the form

$$|\sigma_{c_1}(R_1)\bowtie_{R_1.A=R_2.A}\sigma_{c_2}(R_2)|$$

- 1D statistics + Independence Assumption (IA) are commonly used in practice
 - But IA is often violated in real-world data
 - Potentially results in suboptimal query plans
- Lifting IA requires multidimensional statistics that are
- accurate
- efficiently computable
- easy to maintain and construct
- Prior approaches do not provide all these characteristics
- Generalization to n-way joins and selections on join predicate are covered in the paper

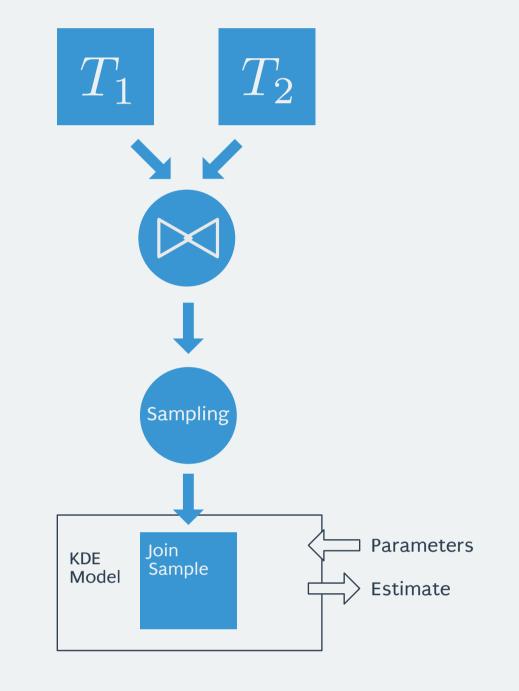

Method 1: Join Model

- KDE model constructed from the join result
 - Sampling from the join result
 - Requires exact or a good estimate of the join size

Joins: Selections:

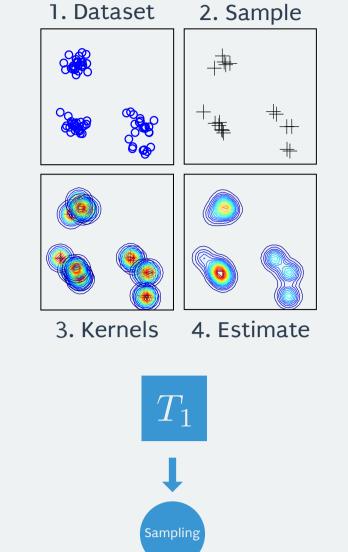

Handled implicitly by sampling
Handled explicitly during estimation

- Very accurate estimates
- Cheap model evaluation
- Limited to one particular join
- More expensive model construction and maintenance

KDE for Selectivity Estimation

- Kernel Density Estimation (KDE)
 - Multivariate probability density estimation
 - Based on a uniform data sample
 - Smoothing by centering kernel functions on sample points
 - Smoothing controlled by bandwidth parameter
- KDE has been applied to range filters over base tables
 - Good accuracy
 - Hybrid between sampling and histograms
 - Bandwidth selection based on query feedback
 - Learning estimator
 - Efficiently trainable and evaluable
 - Suitable for GPU acceleration
- In this publication: Extension to joins that are subject to selections

Method 2: Table Model

- Estimates are computed by combining base table KDE models
 Joining the estimated distributions
- Joins: Handled explicitly during estimationSelections: Handled explicitly during estimation
- Naive implementation: Pass over the cross product of samples
 Pruning techniques are required
- Cheap model construction & maintenance
- General model: Supports joins, base table selections
- More expensive estimate computation

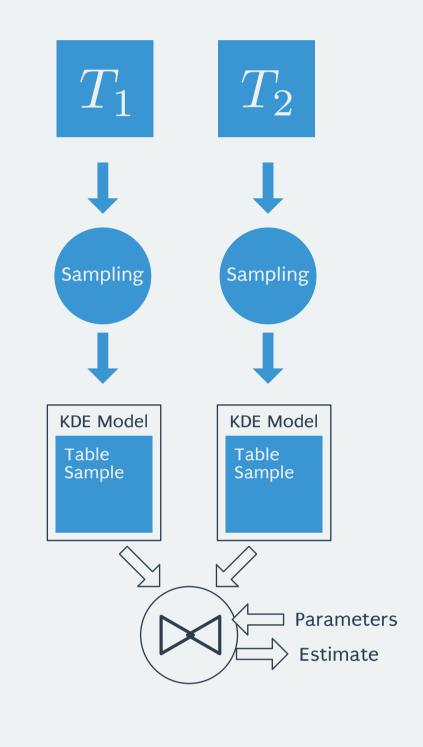

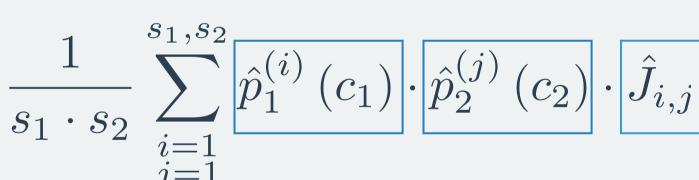

Table Model: Pruning Techniques

• The estimates are computed given the following equation (EQ1):

- ${\bf \cdot}$ Sum over cross product of samples with size s_1 and s_2
- Invariant Contributions
 - Contribution of each sample point w.r.t. selection predicate
 - Depend on only one side of the cross product

• Cross Contribution

- Join-specific contribution
- Depends on both sides of the cross product
- Distance function between the values on join attributes

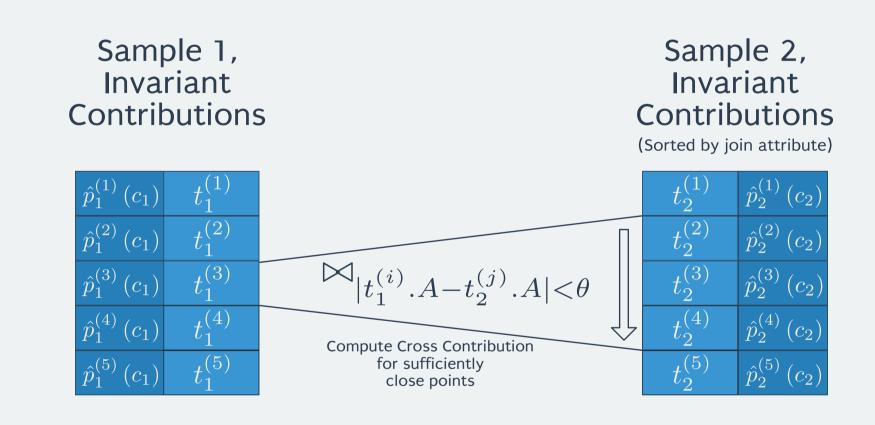

Sample Pruning

- Computes invariant contributions for every sample point
- Removes sample points with negligible contributions
- Reduces the number of input tuples to the cross product

$\begin{array}{c} \text{Sample 1,} \\ \text{Invariant} \\ \text{Contributions} \end{array} \begin{array}{c} \text{Pruned Sample 1,} \\ \text{Invariant} \\ \text{Contributions} \end{array} \\ \\ \hline t_1^{(1)} \\ \hline t_1^{(2)} \\ \hline t_1^{(3)} \\ \hline t_1^{(4)} \\ \hline t_1^{(5)} \end{array} \begin{array}{c} \hat{p}_1^{(1)}(c_1) & t_1^{(1)} \\ \hline \hat{p}_1^{(2)}(c_1) & t_1^{(2)} \\ \hline \hat{p}_1^{(3)}(c_1) & t_1^{(4)} \\ \hline \hat{p}_1^{(3)}(c_1) & t_1^{(4)} \\ \hline \hat{p}_1^{(4)}(c_1) & t_1^{(4)} \\ \hline \hat{p}_1^{(4)}(c_1) & t_1^{(4)} \end{array} \\ \\ \hline \hat{p}_1^{(4)}(c_1) & t_1^{(4)} \\ \hline \hat{p}_1^{(5)}(c_1) & t_1^{(5)} \\ \hline \hat{p}_1^{(5)}(c_1) & t_1^{(5)} \\ \hline \\ \hat{p}_1^{(5)}(c_1) & t_1^{(5)} \\ \hline \end{array}$

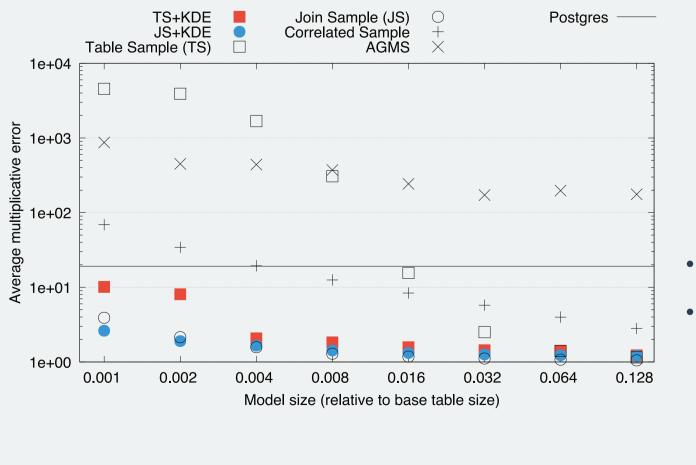

Cross Pruning

- Computes cross contribution only for sufficiently close points
- For each sample point in Sample 1
- a binary search locates sufficiently close tuples in Sample 2Join with range predicate instead of cross product

Evaluation

Estimation Quality

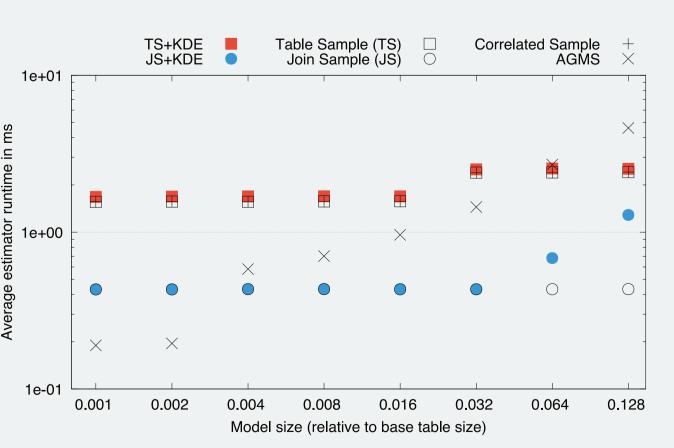

(DMV Q1 Uniform)

- Baselines
 - Postgres: 1D Statistics + Independence Assumption
 - AGMS: Sketch-based approach
 - Table/Join Sample: Uniform sample evaluation
 - Correlated Sample: Nonuniform sample evaluation
- KDE-based estimators trained on 100 workload queries
- KDE-based estimators
 ... outperform plain samples for smaller models
 - ... converge with plain samples for larger models
 - ... converge with plain samples for larger mode
 - ... outperform other baselines in most cases

(IMDB Q1 Distinct)

Estimator Runtime

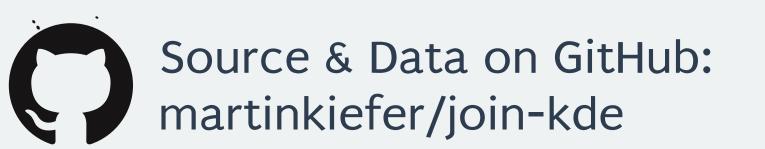

- Setup
- GPU implementations of all estimators
- NVIDIA GTX 980
- OpenCL
- TS+KDE runtime increase is subquadratic
 Pruning techniques are effective
- Pruning techniques are effective
- Framework overhead dominates for smaller models
 Overhead for kernels can become significant
- Here: JS+KDE for sizes 0.064, 0.128
